The Case for Sterile Neutrinos

- A number of recent (and not so recent) results seem to indicate the possibility of sterile neutrinos.
- Evidence stems from a variety of sectors:
 - Cosmology
 - Short-baseline (LSND/MiniBooNE)
 - Reactor anomaly
 - Gallex / SAGE Calibration source
- All suggestive, but no “smoking gun” accepted by the community at the moment.

The Case for Sterile Neutrinos

- A number of recent (and not so recent) results seem to indicate the possibility of sterile neutrinos.
- Evidence stems from a variety of sectors:
 - Cosmology
 - Short-baseline (LSND/MiniBooNE)
 - Reactor anomaly
 - Gallex / SAGE Calibration source
- All suggestive, but no “smoking gun” accepted by the community at the moment.

A Smoking Gun, yes, but how?

- Such anomalous observations warrant further experimental verification, and to a certain degree that occurs and continues to occur
- Example. LSND \rightarrow MiniBooNE.
- Similar follow-up experiments also planned for the reactor anomaly.

- What do we want from a “smoking gun”?
- Evidence that it is *sterile*.
- Evidence that it is *oscillations* (length/energy dependence).

$$\mathcal{P}(\nu_a \rightarrow \nu_s) = 1 - \sin^2(2\theta_s) \sin^2\left(1.27 \Delta m_s^2 \frac{L}{E_\nu}\right)$$

The Argument for Coherent Scattering

- Coherent scattering allows to probe neutrinos using a *neutral current* channel; oscillation signature would be clear sign of active \rightarrow sterile mixing.
- Previous evidence mainly in energy. Uses distance (oscillometry) instead, same detector:
 - For $\Delta m^2 \sim 1 \text{ eV}$
 - $L \sim \mathcal{O}(1 \text{ meter})$; $E_\nu \sim \mathcal{O}(1 \text{ MeV})$
 - Simpler if just source is monochromatic.

The Argument for Coherent Scattering

- Coherent scattering allows to probe neutrinos using a *neutral current* channel; oscillation signature would be clear sign of active \rightarrow sterile mixing.
- Previous evidence mainly in energy. Uses distance (oscillometry) instead, same detector:
 - For $\Delta m^2 \sim 1 \text{ eV}$
 - $L \sim O(1 \text{ meter})$; $E_\nu \sim O(1 \text{ MeV})$
 - Simpler if just source is monochromatic.

- In conjunction with other experiments, could be very powerful (e.g. KamLAND & SNO)

Look for Radioactive Source & Coherent Scattering detector

Oscillometry

Manifestation of oscillations over distance (L) within same experiment very powerful smoking gun. Effect difficult to mimic.

Proposed in conjunction with sterile neutrino searches numerous times in literature.

For 1 MeV neutrinos at 1 eV, implies 1 meter scale.

Oscillometry

Proposed in conjunction with sterile neutrino searches numerous times in literature.

For 1 MeV neutrinos at 1 eV, implies 1 meter scale.

Search for $1/r^2$ deviation

One big obstacle...

$$T_{\max} \leq \frac{E_{\nu}}{1 + \frac{M_A}{2E_{\nu}}}$$

$T_{\max} \leq 50 \text{ eV for Si at } 0.8 \text{ MeV}$

- For neutral current coherent scattering on a silicon target, the maximum kinetic energy is 50 eV. So a threshold of ~10 eV is necessary.
- Methods involving e-h pair detection have very low (or zero) quenching factors at these energies.
- Likewise, energies of at least few eV required to produce scintillation photons. Would yield poor statistics.
- Only remaining option is pure phonon detection.

Scintillation

Ionization

Oscillometry Techniques

Oscillometry Techniques

Neutrino-Electron Scattering, MegaCurie Sources

Allows for much higher thresholds. Sensitive to neutrino magnetic moment.

Henning, arXiv:1011.3811v1; BOREXINO, etc.

Neutral Current Coherent Scattering, MegaCurie Sources

Uses bolometry to probe down to the eV recoil spectrum.

J. Formaggio, E. Figueroa-Feliciano, A. Anderson, hep-ex/1107.3512 (2012). This talk.

Neutrino Sources

Sources	Pros	Cons
Electron Capture	Mono-energetic, can place detector $< 1\text{m}$ from source, ideal for sterile neutrino search	$< 1\text{ MeV}$ energies require very low ($\sim 10\text{ eVnr}$) thresholds, 30 day half-life, costly
Nuclear Reactor	Free, highest flux	Spectrum not well known below 1.8 MeV , site access can be difficult, potential neutron background at research reactors, reactor rarely off for GW power plants
Spallation/Decay at Rest	Higher energies can use higher detector thresholds, timing can cut down backgrounds significantly	SNS funding travails, ESS and Daedalus don't exist, ISODAR will have a low flux requiring large detectors

Neutrino Sources

Sources	Pros	Cons
Electron Capture	Mono-energetic, can place detector $< 1\text{m}$ from source, ideal for sterile neutrino search	$< 1\text{ MeV}$ energies require very low ($\sim 10\text{ eVnr}$) thresholds, 30 day half-life, costly

Spallation/Decay at Rest	Higher energies can use higher detector thresholds, timing can cut down backgrounds significantly	SNS funding travails, ESS and Daedalus don't exist, ISODAR will have a low flux requiring large detectors

The Source

- Ideal mono-energetic sources have been constructed for experiments previously (SAGE, GALLEX), of order 1 MCi activity.
- A compact ³⁷Ar is particularly attractive, since only inner brems photons produced. However, difficult to produce.
- ⁵¹Cr less ideal (but easier to produce) source. Allows for “recharging” for greater yield.

SAGE

$$^{71}\text{Ga} + \nu_e \rightarrow ^{71}\text{Ge} + e^-$$

Use of ³⁷Ar and ⁵¹Cr

Gallex/GNO

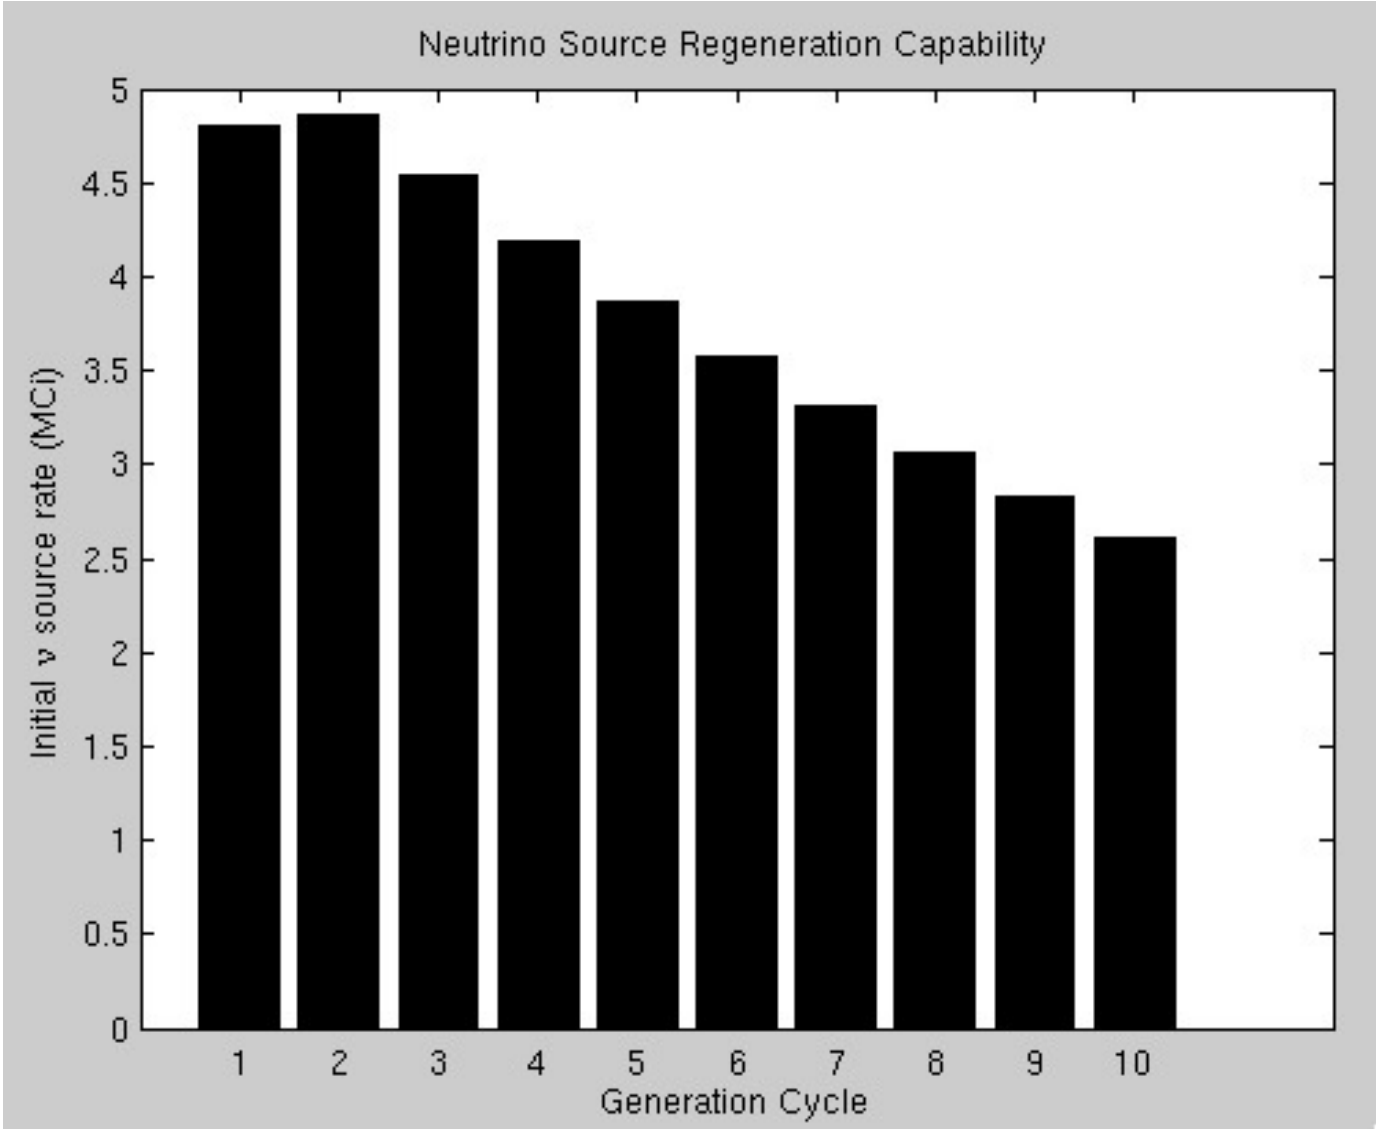

$$^{71}\text{Ga} + \nu_e \rightarrow ^{71}\text{Ge} + e^-$$

Use of ⁵¹Cr

Source	Half-Life	Progeny	Production	E_ν
³⁷ Ar	35.04 days	³⁷ Cl	⁴⁰ Ca(n,α) ³⁷ Ar	811 keV (90.2%), 813 keV (9.8%)
⁵¹ Cr	27.70 days	⁵¹ V	n capture on ⁵⁰ Cr	747 keV (81.6%), 427 keV (9%), 752 keV (8.5%)
⁶⁵ Zn	244 days	⁶⁵ Cu	n capture on ⁶⁴ Zn	1343 keV (49.3%), 227 keV (50.7%)

The Source

- Ideal mono-energetic sources have been constructed for experiments previously (SAGE, GALLEX), of order 1 MCi activity.
- A compact ^{37}Ar is particularly attractive, since only inner brems photons produced. However, difficult to produce.
- ^{51}Cr less ideal (but easier to produce) source. Allows for “recharging” for greater yield.

Recharging ^{51}Cr source (37.6MCi equivalent), M. Pyle

Source	Half-Life	Progeny	Production	E_ν
^{37}Ar	35.04 days	^{37}Cl	$^{40}\text{Ca}(\text{n},\alpha)^{37}\text{Ar}$	811 keV (90.2%), 813 keV (9.8%)
^{51}Cr	27.70 days	^{51}V	n capture on ^{50}Cr	747 keV (81.6%), 427 keV (9%), 752 keV (8.5%)
^{65}Zn	244 days	^{65}Cu	n capture on ^{64}Zn	1343 keV (49.3%), 227 keV (50.7%)

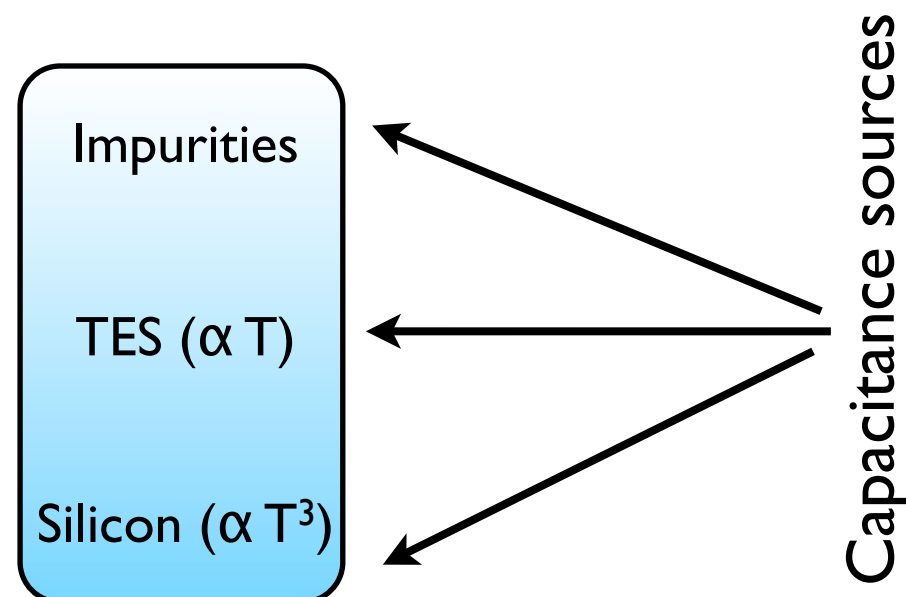

The Detector

- Given historical precedent, we focus on Transition Edge Sensors (TES) as the technology to push down to the 10 eV scale.
- Energy resolution dominated by the total heat capacitance of system (C_{tot}).
- At 15 mK, a 10 eV threshold could be achieved with a system capacitance of $C_{\text{tot}} < 300$ pJ/K.
- Model must include noise sources from other internal decouplings.

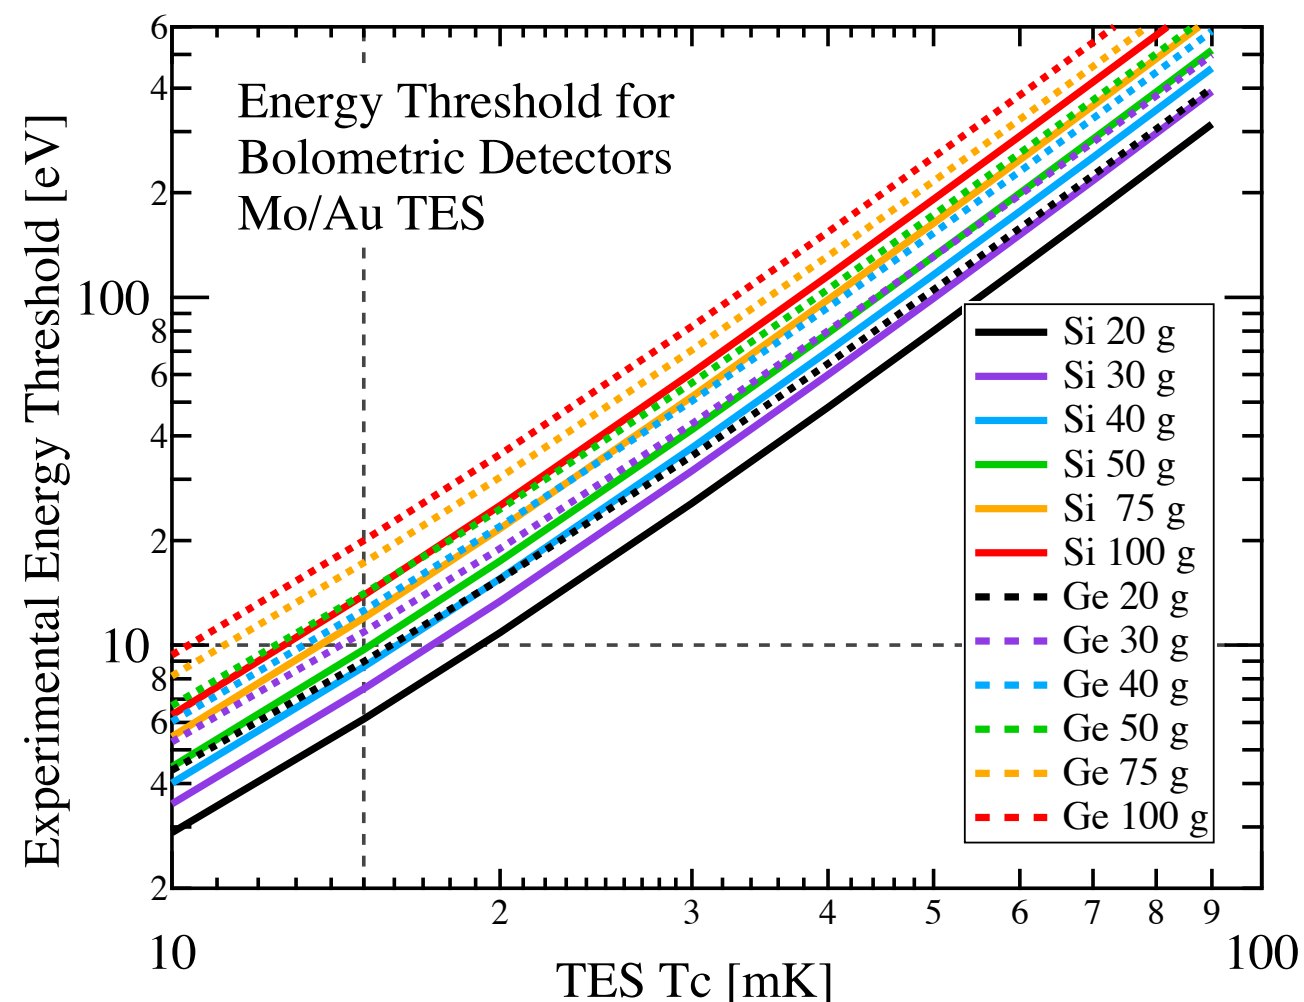

SCUBA II Detector (10,000 pixels, each extremely small)

$$\sigma_E \approx \sqrt{\frac{4k_B T^2 C_{\text{tot}}}{\alpha}} \sqrt{\frac{\beta + 1}{2}}$$

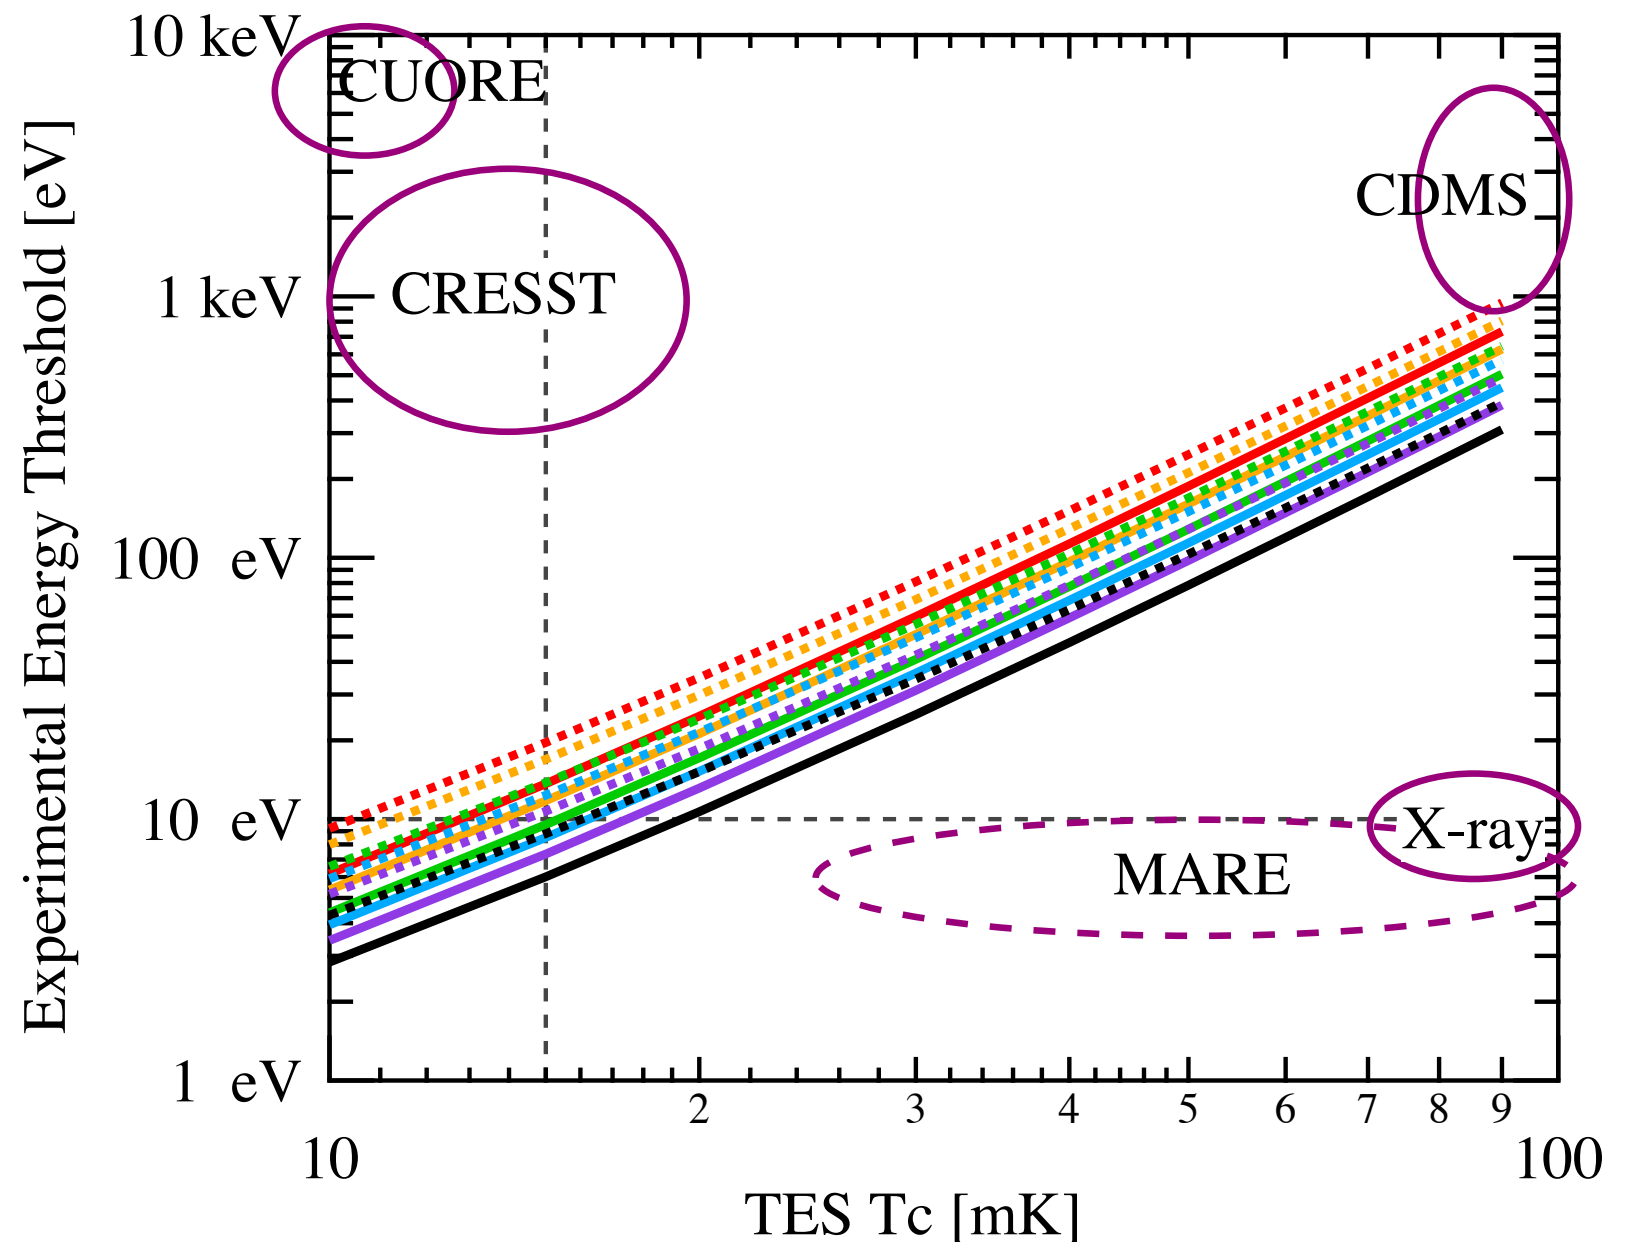

Detector Optimization

- System's mass optimized to reach 10 eV threshold assuming 15 mK temperature.
- Yields 50 g Si (20 g Ge) cube.
- Signal pulses show remarkable linearity.

Precedent

- Knaack and Meibner have achieved low enough impurities ($O(10^{12})$) where Debye heat capacity dominates.
- Using Mo-Au TES, 2 eV resolutions (FWHM) have been achieved, hence used here as well.

- Some existing experiments use similar technology, but are optimized for different parameters, such as mass, resolution, and timing. But no new technology is postulated.

The Array

- Array of 10,000 elements with Ar/Cr source just outside shield (10 cm closest distance). System would be a merger of CUORE-like cryogenic design and SCUBA-II like readout.
- Yields 500 kg Si / 200 kg Ge array.
- Source insertion outside system. Moved for in-situ calibration.

Parameter	Detector Type	
Detector Material	Si	Ge
Atomic Number	28	72.6
$\sigma_0(E_\nu)$ (10^{-42} cm ²)	0.44	3.82
T_{\max}	50.3 eV	19.4 eV
Threshold	10 eV	
Efficiency ($f(E_\nu, T_0)$)	64.2%	23.6%
Detector cube size	28 mm	15.5 mm
Detector Mass	50 g	20 g
Number of Detectors	10,000	
Total Mass	500 kg	200 kg
Yield at 10 cm ($\text{kg}^{-1}\text{day}^{-1}\text{MCI}^{-1}$)	15.28	19.0
Signal Rate at 10 cm	3.82 day ⁻¹	1.90 day ⁻¹

RICOCHET
A Coherent Neutrino Scattering Program

Backgrounds and Systematics

- Backgrounds stem from various sources:
 - Radiogenic impurities (U,Th, ^{60}Co , and ^3H). Most have signatures well above region of interest. Some, like ^3H , have betas that have phase space in ROI.
 - Compton and photo-absorption.
 - Surface photons from atomic transitions.
 - Neutrons (< 0.1 eV/kg/yr in 10-100 keV, from CDMS measurements)
 - Neutrino-elastic scattering (not in energy range)

Estimates from CDMS place background at 40 events/kg/day/keV in the 1-10 keV region.

Leads to 1-2 events/kg/day in ROI

Source	Systematic	
	Global	Shape Only
Source Strength	$\pm 1\%$	-
Cross-section	$\pm 1\%$	-
Detector Variation	$\pm 2\%$	$\pm 2\%$
Absolute Efficiency	$\pm 5\%$	-
Source-Induced Background	$< 1\%$	$< 1\%$
Vertex Resolution	± 2.8 cm	± 2.8 cm
Source Extent	± 4 cm	± 4 cm
Total Systematic	$\pm 5.5\%$	$\pm 2\%$
Statistical (Whole Array)	$\pm 1\%$	

Estimates from CDMS place background at 40 events/kg/day/keV in the 1-10 keV region.

Leads to 1-2 events/kg/day in ROI

Sensitivity Studies

- Wanted to determine what the potential sensitivity of such an experiment for a sterile neutrino at the 1 eV mass splitting scale.
- Array of 10,000 elements with Ar/Cr source just outside shield (10 cm closest distance).
- Measuring time of 300 days (for Ar, equivalent of 50 days signal, 250 days background).
- Background rate of 1 event/kg/day

Results

- Sensitivity study performed on 10,000 element array (500 kg Si, 200 kg Ge) (Ar or Cr source)
- Assumed 300 day measuring time with background rate of 1 event/kg/day.
- Analysis on shape + rate (bulk result from shape)
- Mock signal also tested.

Results

- Sensitivity study performed on 10,000 element array (500 kg Si, 200 kg Ge) (Ar or Cr source)
- Assumed 300 day measuring time with background rate of 1 event/kg/day.

- Assumed 300 day measuring time with background rate of 1 event/kg/day.
- Analysis on shape + rate (bulk result from shape)
- Mock signal also tested.

Alternate Measurements

coherent scattering measurement
 $\sin^2\theta_W$ measurement
dark matter detection

A small scale demonstration (few kg) is beginning to be constructed.

Source acquisition may be difficult, would need to be warranted by
the science.

Use of this technology appears promising, even at the ton scale.

Detector Properties

Parameter	Value	Units	Description
C_{Si}	43.2	pJ/K	Debye heat capacity
C_{TES}	39.8	pJ/K	TES electron heat capacity
G_{ep}	37.5	nW/K	TES-Si thermal conductance
G_{pb}	0.30	nW/K	Si-bath thermal conductance
T_b	7.5	mK	Cold bath temperature
T_c	15	mK	TES temperature
R_o	3	m Ω	Quiescent TES resistance
I_o	18.3	μA	Quiescent TES current
P_o	1.0	pW	Quiescent TES power
$\alpha = \frac{T_c}{R_o} \frac{dR}{dT}$	80	-	TES sensitivity
τ_o	276.7	ms	Natural decay time $C_{\text{tot}}/G_{\text{pb}}$
τ_{eff}	20.0	ms	Response time with TES speedup
τ_{decay}	11.8	ms	Decay time with readout circuit
L	13	μH	Readout inductance

Detector Assumptions

- Each detector is a Si cube ranging in mass from 20–100 g. The heat capacity is determined from Debye theory.
- The conductance between the Si and the cold bath, G_{pb} , can be engineered to give a desired value. The value is chosen to give a thermal impulse response time of 20 ms as measured by the thermometer readout.
- The thermometer is a Mo/Au TES bilayer with a superconducting transition engineered to a specific temperature between 10–100 mK. Mo/Au TES X-ray detectors have achieved resolutions of $\Delta E_{FWHM} = 2$ eV [?].
- The TES heat capacity and electron-phonon coupling are taken from the literature and are a function of the chosen volume of the TES and the temperature.
